## Confusion matrix

Confusion matrix  $M = \{m_{ij}\}_{i,j=1}^C$  shows the number of  $\omega_i$  class objects predicted as belonging to class  $\omega_j$ .

		Estimated classes			
		1	2	...	C
True classes	1	$\left[ \begin{array}{cccc} n_{11} & n_{12} & & \\ n_{21} & n_{22} & & \\ & & \ddots & \\ & & & n_{CC} \end{array} \right]$			
	2				
	...				
	C				

Diagonal elements correspond to correct classifications and off-diagonal elements - to incorrect classifications.

# Example of confusion matrix visualization

## Example of confusion matrix visualization

# Example of confusion matrix visualization

## Example of confusion matrix visualization

- We see here that errors here are concentrated at distinguishing between classes 1 and 2.
- We can
  - unite classes 1 and 2 into new class «1+2»
  - then solve 6-class classification problem
  - separate classes 1 and 2 for all objects assigned to class «1+2» with a separate classifier.

## 2 class case

### Confusion matrix:

		Prediction	
		+	-
True class	+	TP (true positives)	FN (false negatives)
	-	FP (false positives)	TN (true negatives)

$P$  and  $N$  - number of observations of positive and negative class.

$$P = TP + FN, \quad N = TN + FP$$

## 2 class case

### Confusion matrix:

		Prediction	
		+	-
True class	+	TP (true positives)	FN (false negatives)
	-	FP (false positives)	TN (true negatives)

$P$  and  $N$  - number of observations of positive and negative class.

$$P = TP + FN, \quad N = TN + FP$$

Accuracy:	$\frac{TP+TN}{P+N}$
Error rate:	$1\text{-accuracy} = \frac{FP+FN}{P+N}$

## 2 class case

### Confusion matrix:

		Prediction	
		+	-
True class	+	TP (true positives)	FN (false negatives)
	-	FP (false positives)	TN (true negatives)

$P$  and  $N$  - number of observations of positive and negative class.

$$P = TP + FN, \quad N = TN + FP$$

Accuracy:	$\frac{TP+TN}{P+N}$
Error rate:	$1\text{-accuracy} = \frac{FP+FN}{P+N}$

Not informative for skewed classes and one class of interest!

## “Positive class” quality metrics

FPR (error rate on negatives):	$\frac{FP}{N}$
TPR (error rate on positives):	$\frac{TP}{P}$
Precision:	$\frac{TP}{TP+FP}$
Recall:	$\frac{TP}{P}$
F-measure:	$\frac{2}{\frac{1}{Precision} + \frac{1}{Recall}}$
Weighted F-measure:	$\frac{1}{\frac{\beta^2}{1+\beta^2} \frac{1}{Precision} + \frac{1}{1+\beta^2} \frac{1}{Recall}}$

## Class label versus class probability evaluation

- **Discriminability quality measures** evaluate class label prediction.
  - examples: previously mentioned measures: error rate, precision, recall, etc..

## Class label versus class probability evaluation

- **Discriminability quality measures** evaluate class label prediction.
  - examples: previously mentioned measures: error rate, precision, recall, etc..
- **Reliability quality measures** evaluate class probability prediction.
  - Example: probability likelihood:

$$\prod_{i=1}^N \hat{p}(y_i|x_i)$$

- Brier score:

$$\frac{1}{n} \sum_{i=1}^n \sum_{c=1}^C (\mathbb{I}[x_i \in \omega_c] - \hat{p}(\omega_c|x_i))^2$$

- Example when class labels are predicted accurately, but class probabilities - not.

# Table of Contents

## 1 ROC curves

# Bayes decision rule

- Definition:  $\hat{\omega}_i$  means, that «prediction is equal to  $\omega_i$ »
- Loss matrix:

		predicted class	
		$\hat{\omega}_1$	$\hat{\omega}_2$
true class	$\omega_1$	0	$\lambda_1$
	$\omega_2$	$\lambda_2$	0

- $\lambda_1, \lambda_2$  - costs of incorrect classification of objects, belonging to classes  $\omega_1$  and  $\omega_2$  respectively.

# Bayes decision rule

- Expected loss of prediction  $\hat{\omega}_1$ :  
 $L(\hat{\omega}_1) = \lambda_2 p(\omega_2|x) = \lambda_2 p(\omega_2)p(x|\omega_2)/p(x)$
- Expected loss of prediction  $\hat{\omega}_2$ :  
 $L(\hat{\omega}_2) = \lambda_1 p(\omega_1|x) = \lambda_1 p(\omega_1)p(x|\omega_1)/p(x)$
- Bayes decision rule* minimizes expected loss:

$$\hat{\omega}^* = \arg \min_{\hat{\omega}} L(\hat{\omega})$$

- This is equivalent to:  
 $\hat{\omega}^* = \hat{\omega}_1 \Leftrightarrow \lambda_2 p(\omega_2)p(x|\omega_2) < \lambda_1 p(\omega_1)p(x|\omega_1) \Leftrightarrow$

$$\frac{p(x|\omega_1)}{p(x|\omega_2)} > \frac{\lambda_2 p(\omega_2)}{\lambda_1 p(\omega_1)} = \mu$$

# Discriminant decision rules

- Decision rule based on discriminant functions:
  - predict  $\omega_1 \iff g_1(x) - g_2(x) > \mu$
  - predict  $\omega_1 \iff g_1(x)/g_2(x) > \mu$  (for  $g_1(x) > 0, g_2(x) > 0$ )
- Decision rule based on probabilities:
  - predict  $\omega_1 \iff P(\omega_1|x) > \mu$

# ROC curve

- ROC curve - is a function  $\text{TPR}(\text{FPR})$ .
- It shows how the probability of correct classification on positive classes (“recognition rate”) changes with probability of incorrect classification on negative classes (“false alarm”).
- It is build as a set of points  $\text{TPR}(\mu)$ ,  $\text{FPR}(\mu)$ .
- If  $\mu \downarrow$ , the algorithm predicts  $\omega_1$  more often and
  - $\text{TPR} = 1 - \varepsilon_1 \uparrow$
  - $\text{FPR} = \varepsilon_2 \uparrow$
- Diagonal points correspond to random assignment of  $\omega_1$  and  $\omega_2$  with probabilities  $p$  and  $1 - p$ .
- Characterizes classification accuracy for different  $\mu$ .
  - more concave ROC curves are better

# Iso-loss lines

- Define  $\varepsilon_1, \varepsilon_2$  - probabilities of error on objects of class  $\omega_1$  and  $\omega_2$  respectively.
- $1 - \varepsilon_1 = TPR$ ,  $\varepsilon_2 = FPR$
- Expected loss:

$$L = \lambda_2 p(\omega_2) \varepsilon_2 + \lambda_1 p(\omega_1) \varepsilon_1 = \lambda_2 p(\omega_2) \varepsilon_2 - \lambda_1 p(\omega_1) (1 - \varepsilon_1) + \lambda_1 p(\omega_1)$$

- Iso-loss line:

$$(1 - \varepsilon_1) = \frac{\lambda_2 p(\omega_2)}{\lambda_1 p(\omega_1)} \varepsilon_2 + \frac{\lambda_1 p(\omega_1) - L}{\lambda_1 p(\omega_1)}$$

- In the optimal point iso-loss line is tangent to the ROC curve with slope of the curve equal to  $\frac{\lambda_2 p(\omega_2)}{\lambda_1 p(\omega_1)}$

# Comparison of classifiers using ROC curves

# Comparison of classifiers using ROC curves

How to compare different classifiers?

# Area under the curve

- AUC - area under the ROC curve:
  - global quality characteristic for different  $\mu$
  - $AUC \in [0, 1]$ 
    - $AUC=0.5$  - equivalent to random guessing
    - $AUC=1$  - no errors classification.
  - AUC property: it is equal to probability that for 2 random objects  $x_1 \in \omega_1$  and  $x_2 \in \omega_2$  it will hold that:  
 $\hat{p}(\omega_1|x_1) > \hat{p}(\omega_2|x)$

# Bayes decision rule with uncertainty about $\lambda_1$ and $\lambda_2$

- Predefined  $\lambda_1, \lambda_2$ : too specific.
  - estimate losses associated with yield point estimates of classifiers
- Undefined  $\lambda_1, \lambda_2$ : too broad
  - compare AUC of different classifiers
- LC index - classifier comparison in intermediary case:

# LC index

- 1 Scale  $\lambda_1$  and  $\lambda_2$  so that  $\lambda_1 + \lambda_2 = 1$
- 2 define  $\lambda_1 = \lambda$ ,  $\lambda_2 = 1 - \lambda$
- 3 for each  $\lambda \in [0, 1]$  calculate
$$L(\lambda) = \begin{cases} +1 & \text{if 1st classifier is better} \\ -1 & \text{if 2nd classifier is better} \end{cases}$$
- 4 define probability density distribution of  $\lambda$ :  $p(\lambda)$  (for example, from “triangular” class)
- 5 select classifier 1 if  $\int_0^1 L(\lambda)p(\lambda)d\lambda > 0$  and classifier 2 otherwise.
